## ABSTRACT

In response to the evolving landscape of modern military operations, the development of advanced technologies plays a pivotal role in enhancing security measures and situational awareness. This technical report presents the design, development, and implementation of an autonomous military robot specifically engineered for room scanning and intruder elimination. Leveraging cutting-edge robotics, artificial intelligence, and sensing technologies, the system autonomously navigates enclosed spaces, generates accurate 2D maps, and responds effectively to unauthorized intrusions in real-time. The report provides a comprehensive overview of the system architecture, including hardware specifications, software algorithms, and integration methodologies. Furthermore, it outlines the testing protocols, validation procedures, and performance evaluations conducted to ensure the system's reliability, accuracy, and safety in operational scenarios. By amalgamating state-of-the-art technologies, this project contributes to the advancement of military capabilities in reconnaissance and security missions, offering enhanced protection for personnel and assets. The abstract encapsulates the project's objectives, methodologies, and significance, providing a succinct overview of the technical advancements achieved in autonomous military robotics.

## 1.0. INTRODUCTION

In modern military operations, the need for advanced surveillance and defense mechanisms has become increasingly paramount. The evolution of robotics and artificial intelligence presents an opportunity to enhance situational awareness and security measures. In response to this demand, this technical report outlines the design, development, and implementation of an autonomous military robot tasked with the dual objectives of room scanning and intruder elimination.

The primary objective of this project is to create a robust and efficient system capable of autonomously scanning enclosed spaces, generating accurate 2D maps of the environment, and responding effectively to the presence of unauthorized individuals. The integration of cutting-edge technologies such as sensors, computer vision, and machine learning algorithms enables the robot to navigate complex environments, identify potential threats, and take appropriate actions in real-time.

This report will provide a comprehensive overview of the various components and subsystems incorporated into the robot's design, including hardware specifications, software architecture, and algorithmic implementations. Additionally, it will detail the methodologies employed for testing, validation, and performance evaluation to ensure the system's reliability, accuracy, and safety in operational scenarios.

By combining state-of-the-art robotics with advanced AI capabilities, this project aims to contribute to the enhancement of military capabilities in reconnaissance and security missions. The development of an autonomous robot capable of seamlessly scanning rooms and neutralizing intruders represents a significant advancement in defense technology, offering enhanced protection for personnel and assets in diverse operational environments.

Throughout this report, key design considerations, technical challenges, and future directions for improvement will be addressed, providing insights into the development process and potential avenues for further research and development in the field of autonomous military robotics.

## 2.0. CAD MODEL

### 2.1. Renders

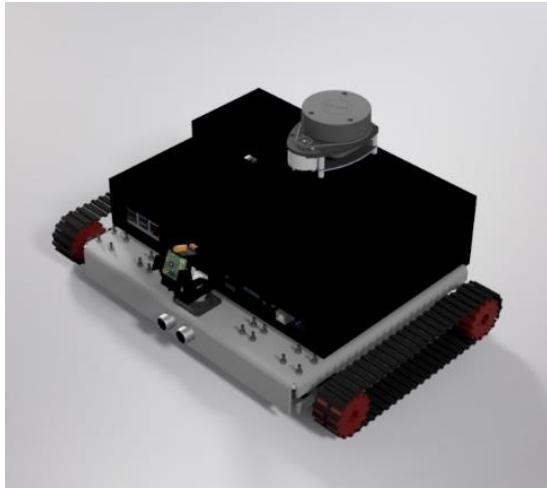

Figure 6 Full Render View 1

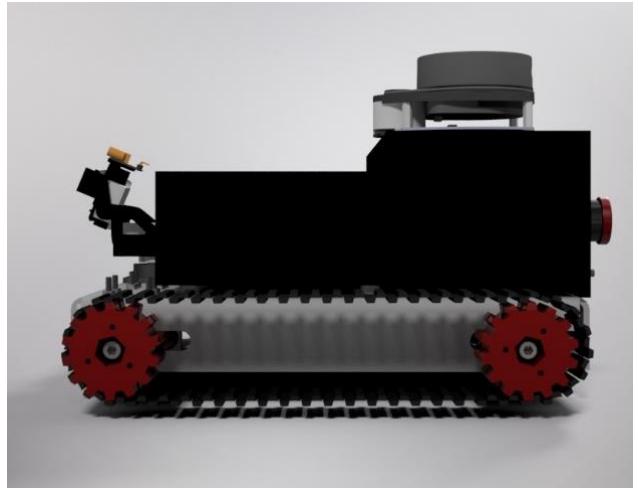

Figure 5 Full Render View 2

Figure 4 Full Render View 3

Figure 3 Full Render View 4

Figure 2 Full Render View 5

## 2.2. Sensors & Cameras

1. Lidar is a remote sensing technology that uses lasers to measure distances and create precise 2D maps of the surrounding environment.

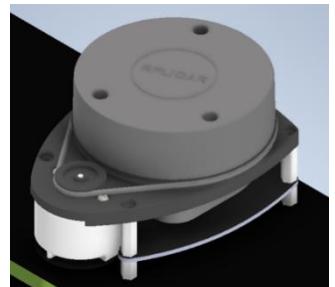

Figure 7 Lidar

2. Ultrasonic sensors are used for distance measurement and object detection. They work by emitting high-frequency sound waves and measuring the time it takes for the waves to bounce back after hitting an object. This information is then used to calculate the distance to the object.

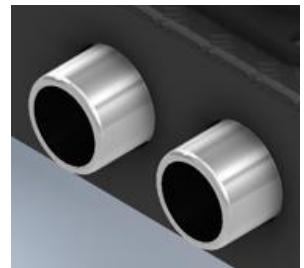

Figure 8  
Ultrasonic sensor

3. A motor encoder is a device used to measure the position, speed, and direction of a motor shaft. It consists of a sensor that detects the rotation of the motor shaft and provides feedback in the form of electrical signals.

Figure 9 Motor  
Encoder

4. A camera in a robot serves as an essential sensory component, enabling visual perception and recognition of the surrounding environment. It captures images or video footage that can be processed and analyzed by the robot's algorithms. The camera provides valuable information for tasks such as object detection, recognition, tracking, navigation, and mapping.

Figure 10  
Camera

### 2.3. Actuators

1. A DC motor is responsible for the motion of the Lidar while rotating.

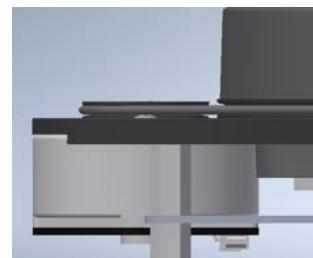

Figure 11 DC Motor

2. A DC motor and its encoder is responsible for generating and controlling the wheels' motion which will move the whole robot.

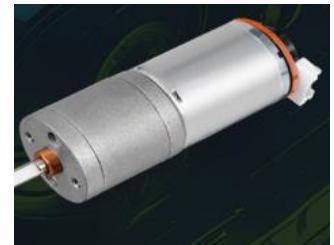

Figure 12 DC motor  
2

3. Servo motor is used to control the motion of the camera

Figure 13  
Servo Motor

## 2.4. Mechanical Consideration & Fixation

### 2.4.1. Metal chassis

The chassis design is brilliant as it has small thickness to provide a light weighted chassis.

Also we chose to use a metal chassis to add rigidity, help the chassis overcome heavier loads and unfortunate circumstances.

Figure 14 Metal Chassis

### 2.4.2. Front wheel assembly

The motor is mounted to the floor using a custom holder. Its shaft, which holds a bearing, is connected to an extension rod that links to a hexagonal coupler fitted directly into the wheel.

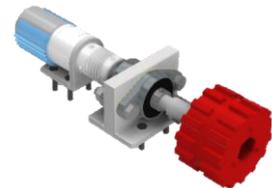

Figure 15 Front Wheel

### 2.4.3. Rear wheel assembly

Using a custom holder. Its shaft, which holds a bearing, is connected to an extension rod that links to a hexagonal coupler fitted directly into the wheel.

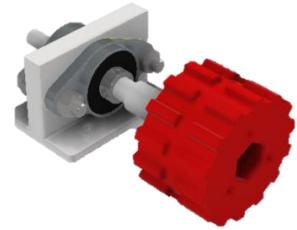

Figure 16 Rear wheel

## 3.0. STRESS ANALYSIS

### 3.1. Von Mises Stress

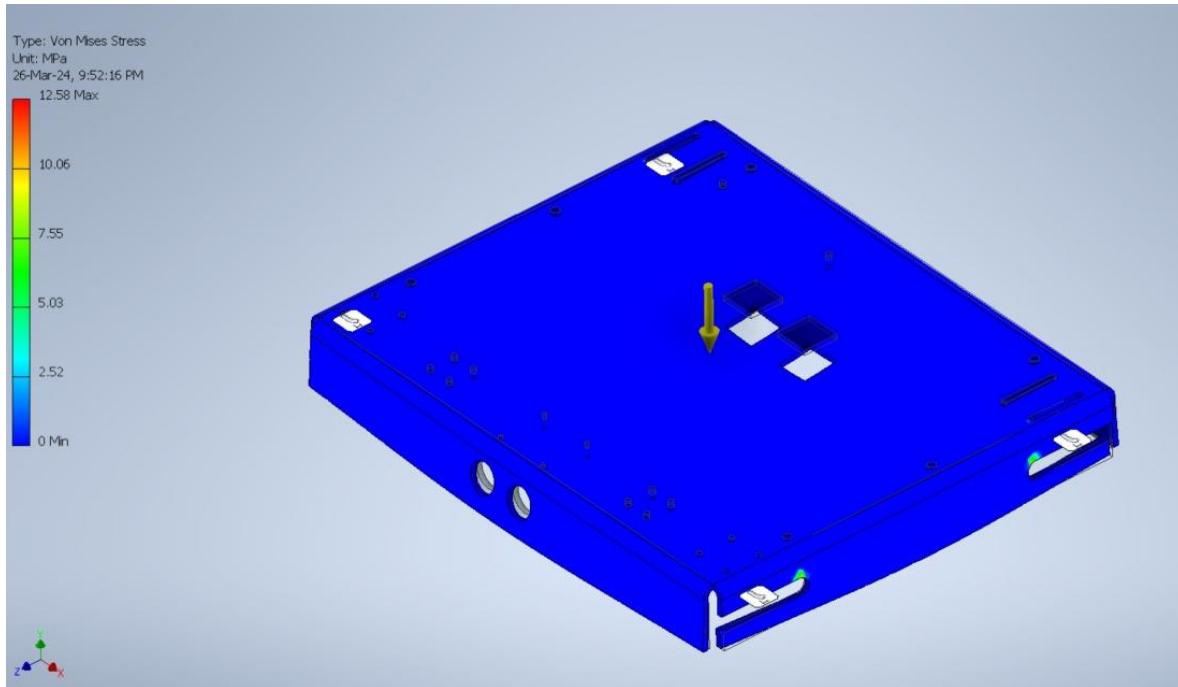

Figure 19 Von Mises Stress

### 3.2. Total Displacement

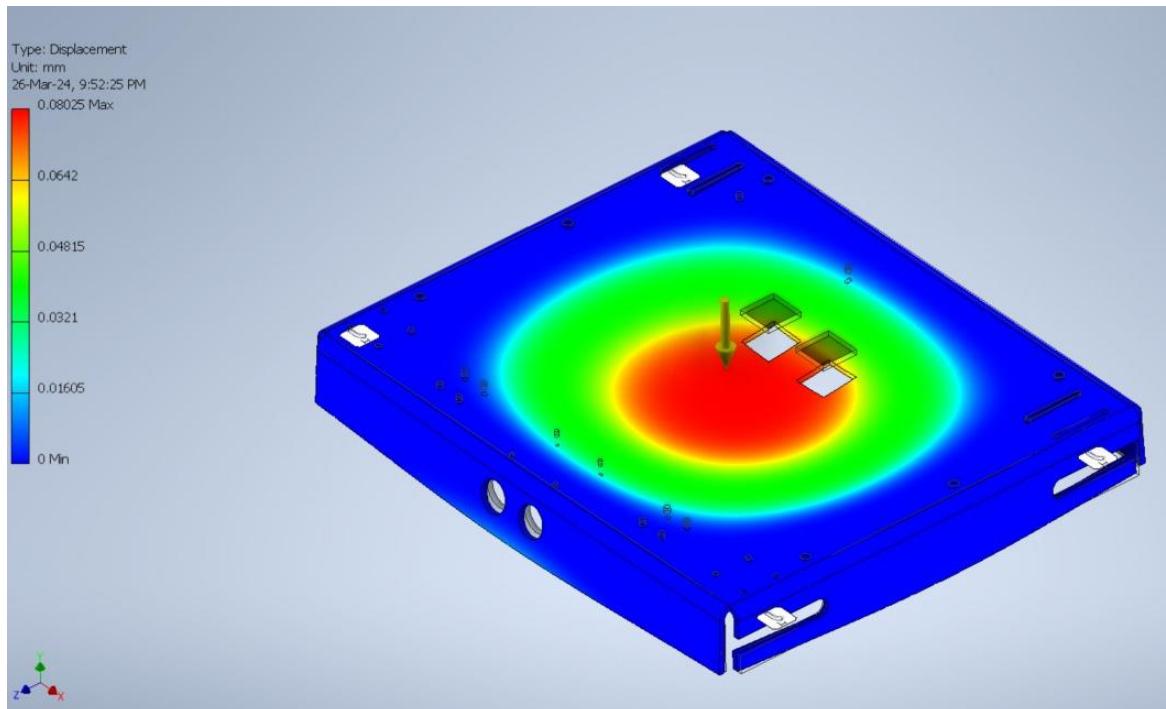

Figure 20 Total Displacement stress

## 4.0. ELECTRIC COMPONENTS

### 4.1. Raspberry Pi 4

A small, affordable single-board computer with GPIO pins, running a Linux-based OS, suitable for a wide range of projects from basic computing to IoT applications.

Figure 21 Raspberry Pi

### 4.2. Arduino Mega

An enhanced version of Arduino Uno with a larger number of input/output pins, suitable for complex projects requiring more connections.

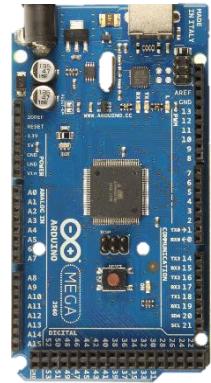

Figure 22  
Arduino  
Mega

### 4.3. Arduino Uno

A versatile microcontroller board with digital and analog input/output pins, ideal for prototyping and DIY projects.

Figure 23 Self  
made Arduino  
Uno

### 4.4. Motor driver (Cytron)

An electronic module that interfaces between a microcontroller (like Arduino) and electric motors, enabling precise control over speed and direction.

Figure 24  
Cytron

#### 4.5. Battery

Rechargeable Battery 10000mA.

Figure 25 Battery

#### 4.6. Power Circuit

Responsible for power distribution to all electric components and boards.

Figure 26 Power Circuit

#### 4.7. Kill Switch

Emergency stopping the robot.

Figure 27 Kill Switch

Figure 28 On/Off Switch

## 5.0. PCB Design

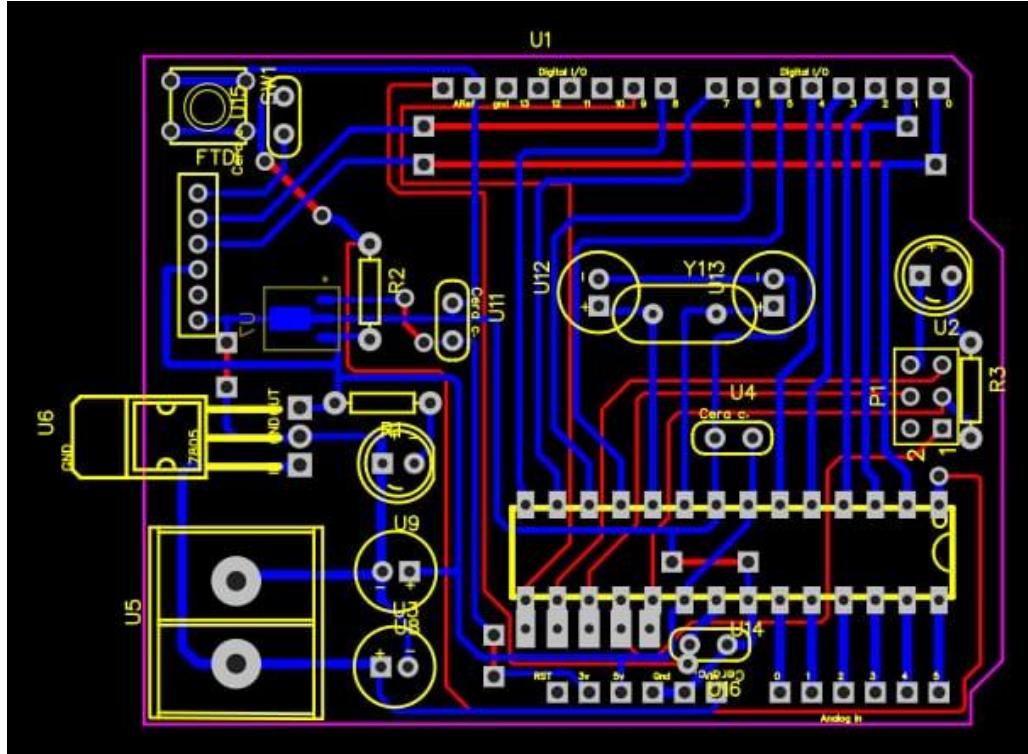

Figure 29 PCB Design

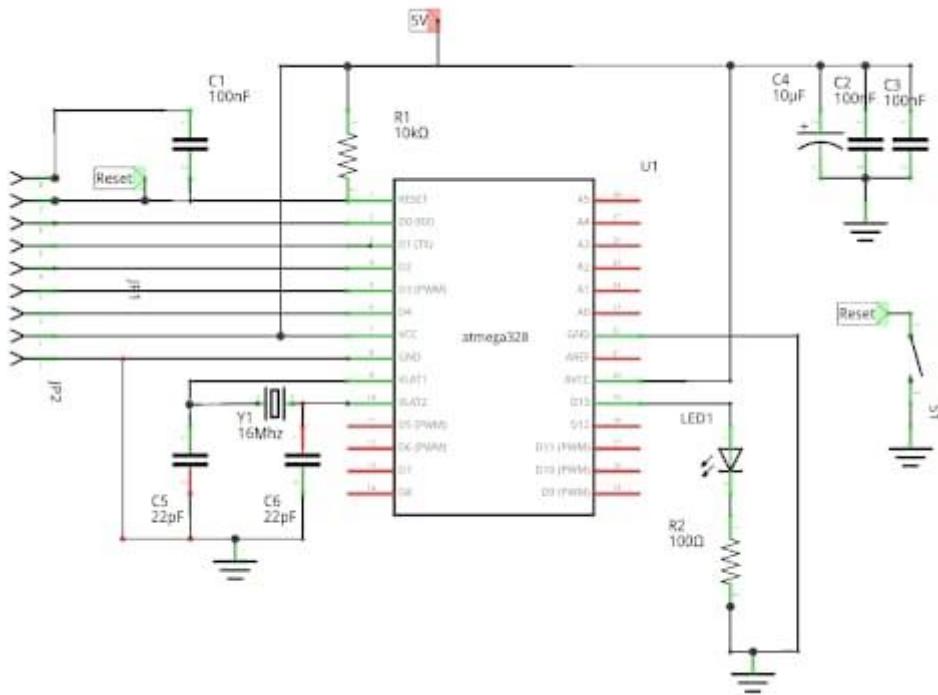

Figure 30 PCB circuit

## 6.0. ACTUATOR SIZING

### 6.1. Using Software

#### 1. Define contact between the wheels and the ground plate

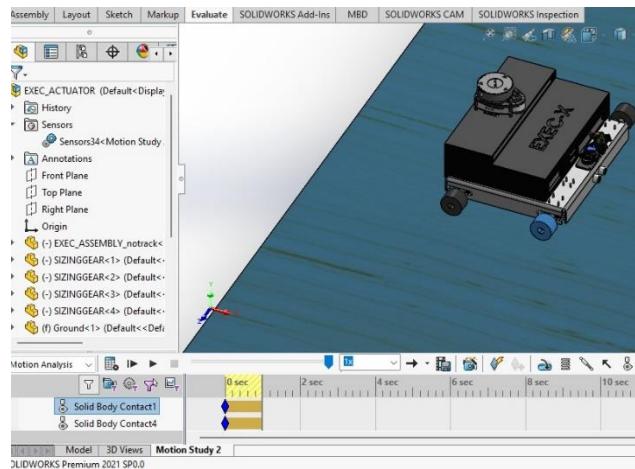

Figure 32 Right Front Wheel Contact w/ ground

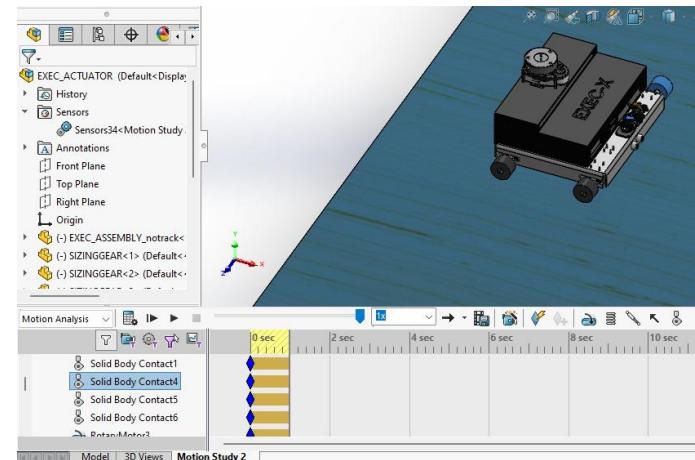

Figure 31 Left Front Wheel Contact with Ground

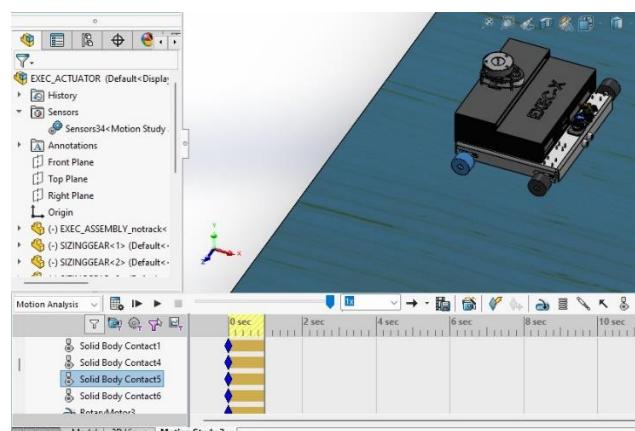

Figure 34 Right Rear Wheel Contact with Ground

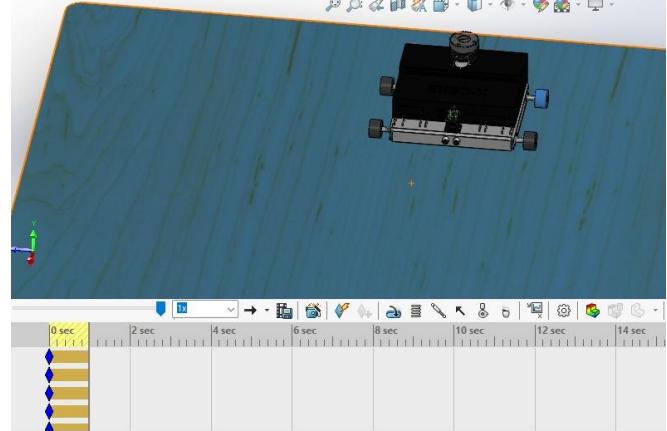

Figure 33 Left Rear Wheel Contact with Ground

2. Define existence of 2 motors driving front wheels as follows, select rotary motor by default, select cylindrical face on the wheel as the first selection, select the robot body as the third selection to be the component that the wheel moves relative to.

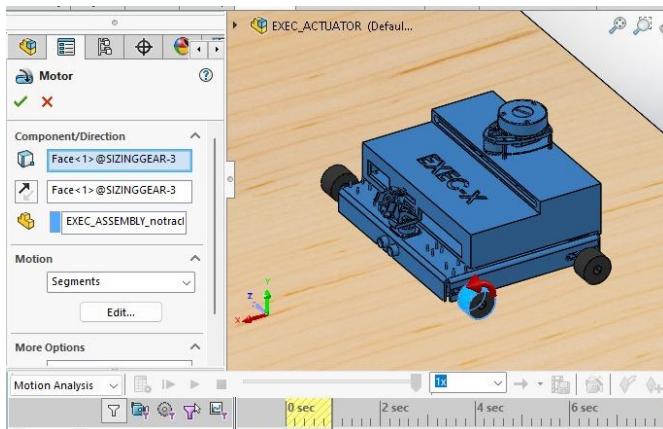

Figure 35 Define Motor for Left Front Wheel

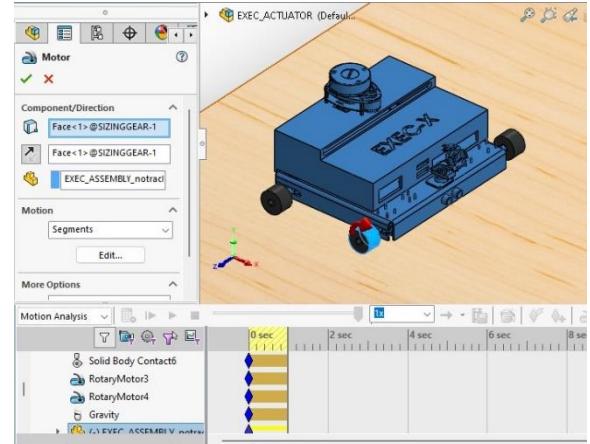

Figure 36 Define Motor for Left Front Wheel

3. Motor desired motion profile can be set from the motion section, for this simulation we will set it as trapezoidal motion profile.

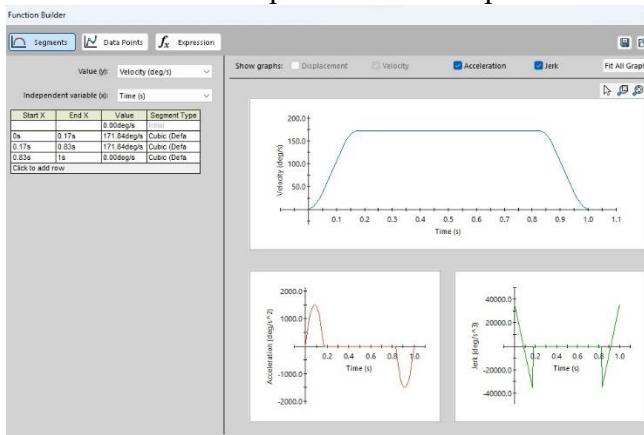

Figure 37 Trapezoidal Motor Motion Profile

4. Adjust the gravity direction to be in negative Y direction

Figure 38 Gravity Direction

5. To view motor torque, change “Basic motion” to “motion analysis”, then click on plots and results and choose the following option

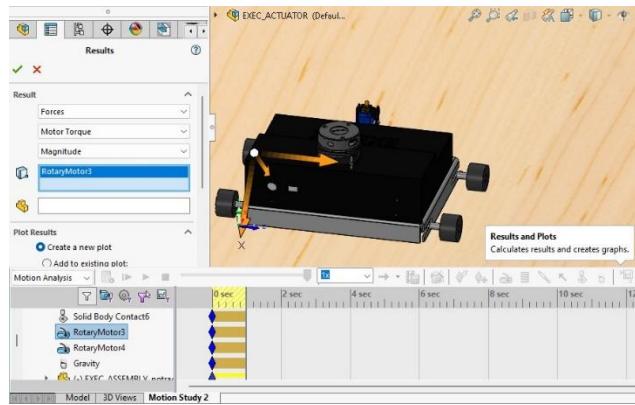

Figure 39 Setting Results and Plots Options

6. Create a sensor to evaluate the RMS torque, from evaluate tab choose sensors, then set the following options

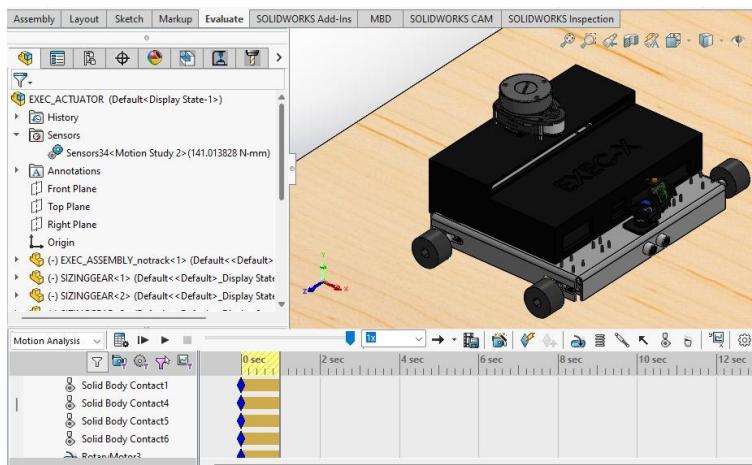

Figure 40 RMS Torque Sensor

## 6.2. Using Manual Calculations

### Actuator Sizing

$$F_a = \frac{1}{2} \times C_d \times \rho \times A_f \times v^2$$

$$= \frac{1}{2} \times 0.1 \times 1.2 \times (0.4 \times 0.28) \times 0.1^2$$

$$= 6.72 \times 10^{-5} \sim \text{negligible}$$

$$F_{\text{rolling}} = M_r \times m g = 0.15 \times 5 \times 9.81 = 7.3575$$

$$\therefore T_R = 7.3575 \times 0.04 = 0.2943$$

$$T_m = T_R + J \ddot{\theta}$$

$$J_{\text{tot}} = J_m + J_{\text{equivalent}} + J_{\text{mass}} + J_{\text{belt}}$$

$$J_{\text{mass}} = \frac{m \times r^2}{\eta \times N^2} = \frac{5 \times 40^2}{0.9 \times 1^2} = 8888.89 \text{ kg.mm}^2$$

$$J_{\text{belt.}} = m r^2 = 0.065 \times 40^2 = 104 \text{ kg.mm}^2$$

$$J_m = 888.89 \text{ kg.mm}^2$$

$$J_{\text{equivalent}} = \frac{1}{2} m r^2 = \frac{1}{2} \times 0.025 \times 40^2 = 20 \text{ kg.mm}^2$$

Figure 41 Calculations 1

$$d = 10 \text{ cm}$$

, Time = 1 sec.

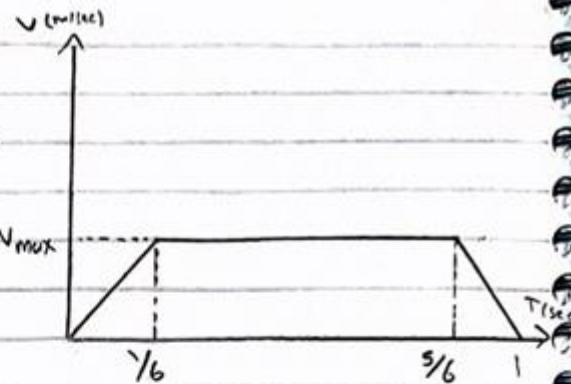

$$2 \times \frac{1}{2} \times v_{max} \times \frac{1}{6} + v_{max} \times \frac{2}{3} = 10 \text{ cm}$$

$$\therefore v_{max} = 12 \text{ cm/sec}$$

$$\omega_{max} = \frac{120}{40} = 3 \text{ rad/sec}$$

$$= 28.64 \text{ rpm}$$

$$\alpha = \frac{3}{\frac{1}{6}} = 18 \text{ rad/sec}^2$$

$$\therefore J_{max} = 3888.39 + 388.89 + 104 + 20 = 9901.78 \text{ kg.mm}^2$$

$$\alpha = 18 \text{ rad/sec}^2$$

$$\therefore T_m = T_R + J\alpha = 0.2943 + 18 \times (9901.78 \times 10^{-6}) = 0.4725 \text{ Nm}$$

$$T_m = T_R - J\alpha = 0.2943 - 18 \times (9901.78 \times 10^{-6}) = 0.11606 \text{ Nm}$$

$$T_{rms} = \sqrt{\frac{0.4725^2 \times \frac{1}{6} + 0.2943^2 \times \frac{2}{3} + 0.11606^2 \times \frac{1}{6}}{1}} = 0.31176 \text{ Nm}$$

$$\text{For only one motor} = \frac{1}{2} \times 0.31176 = 0.15588 \text{ N.m.}$$

Figure 42 Calculations 2

## 7.0. FLOWCHARTS

### 7.1. Explanation

The flowchart illustrates the connectivity of our electrical components, delineating their roles and interactions within the system architecture. Initially, the Raspberry Pi establishes a connection with the LiDAR sensor, pivotal for mapping and localization tasks. This communication occurs via UART, facilitating seamless data exchange. Additionally, the Raspberry Pi interfaces with the Camera v1.3, designated for human detection purposes, utilizing the MIPI camera serial interface protocol. Power is supplied to the Raspberry Pi through an external power bank, ensuring continuous operation.

Furthermore, a custom Arduino Uno board is integrated with an ultrasonic sensor and servo motors. The ultrasonic sensor assumes responsibility for obstacle detection, contributing to the system's navigational capabilities. Simultaneously, the servo motors govern the motion of the camera, enhancing its agility and versatility. An Arduino Mega board is linked with the Citron motor driver, tasked with motor control functions. Notably, the motor incorporates an encoder to capture positional data, transmitted to the Arduino Mega via the I2C communication protocol.

Both the Arduino Uno and Arduino Mega boards are powered by a 10000mA battery source, ensuring sufficient energy for sustained operation. Moreover, they establish communication with the Raspberry Pi via UART, facilitating coordinated actions and data exchange between the components. This systematic arrangement of components and communication protocols ensures the efficient functioning of the system, enabling robust performance and adaptability to diverse operational scenarios.

    }
}

```

#### Explanation Of Code :

This code sets up two motors, reads their speeds using encoders, filters the speed data, and applies PID control to maintain a set speed for both motors. Here's a breakdown of the key parts of your code:

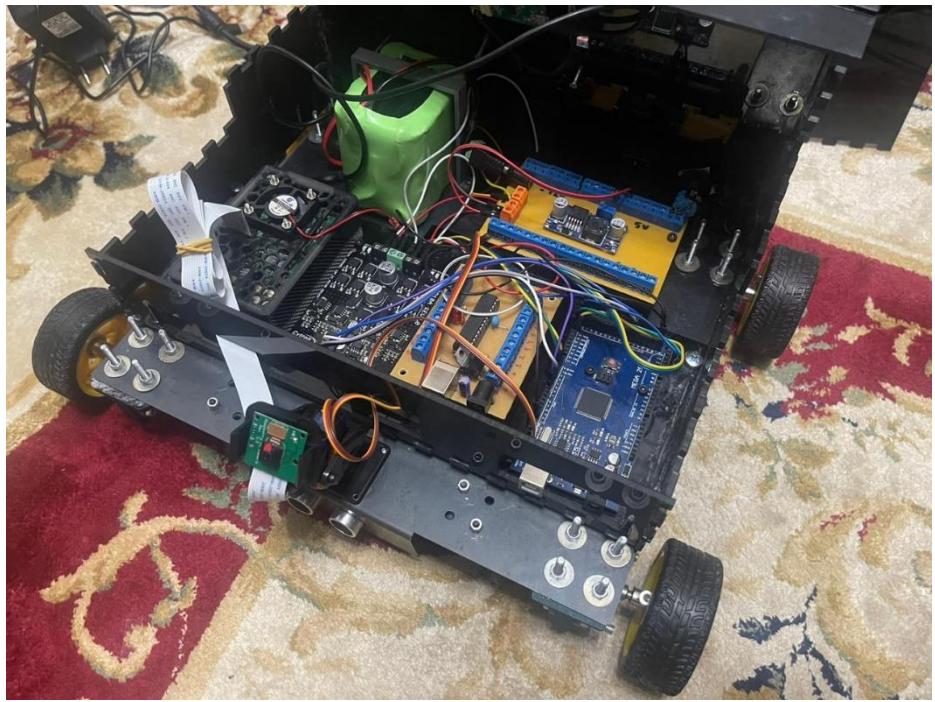

- 1. Motor Control Pins:** Define the pins for controlling the motors (PWM for speed control and direction pins).
- 2. Encoder Pins:** Define the pins for reading encoder signals from the motors to measure their speed.
- 3. Variables:** Define variables for encoder counts, motor speeds, PID parameters, and filter coefficient.
- 4. PID Object:** Create a PID object for controlling the motors based on the encoder feedback.
- 5. Setup Function:** Set up the serial communication, motor control pins, encoder pins, interrupts for encoder readings, and initialize the PID controller.

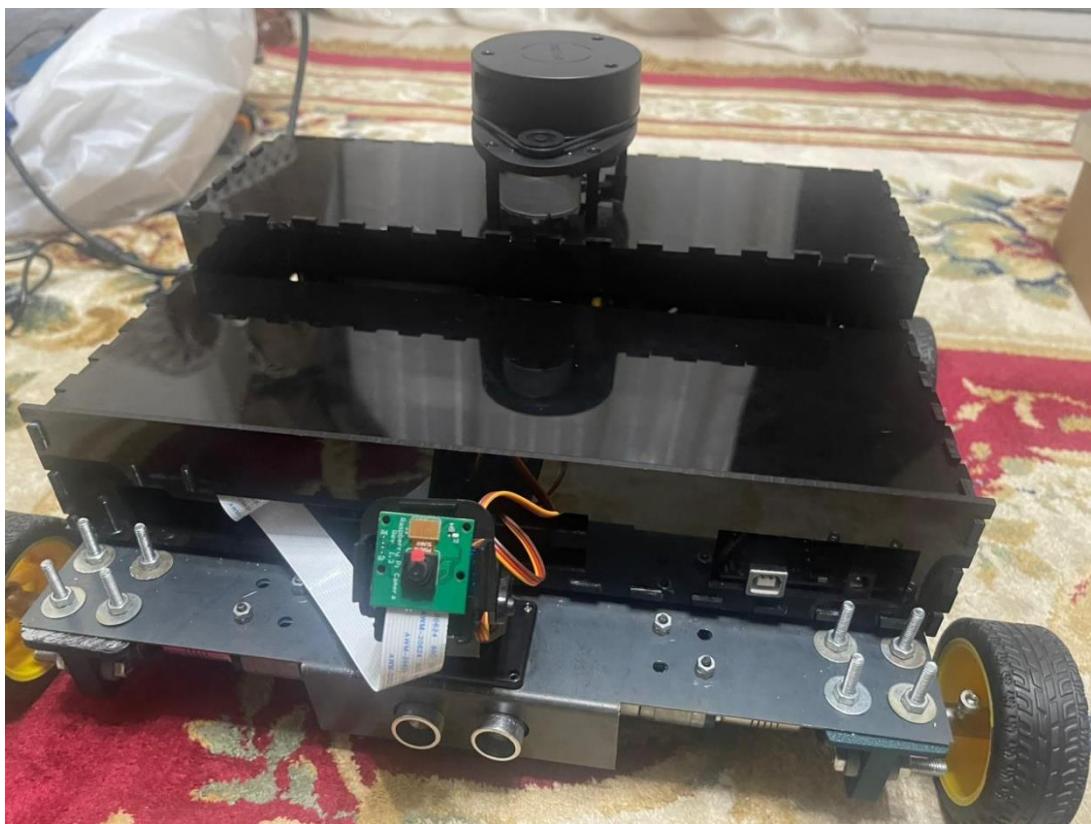

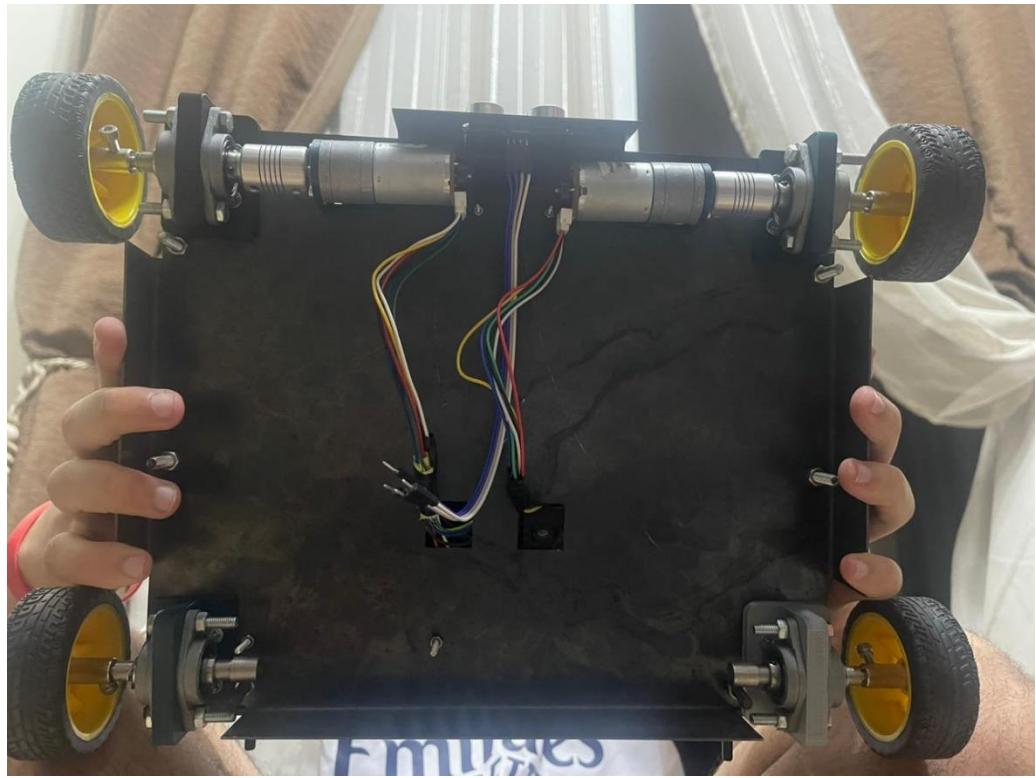

6. **Loop Function:** Continuously read the encoder counts, calculate motor speeds, apply a low pass filter to smooth out noise, compute the PID output, and control the motor speeds using PWM.
7. **Encoder Interrupt Service Routines (ISRs):** Increment or decrement the encoder counts based on the encoder signals.

This code provides a basic framework for implementing PID-controlled motor speed using encoders. You may need to adjust the PID parameters and other settings based on your specific motor and system requirements.

## 12.0. Robot Hardware Implementation

## 13.0. Navigation

### Navigation Using LiDAR and Hector SLAM

#### 1. LiDAR (Light Detection and Ranging):

LiDAR is a remote sensing method that uses light in the form of a pulsed laser to measure variable distances to the Earth. These light pulses, combined with other data recorded by the system, generate precise, three-dimensional information about the shape of the Earth and its surface characteristics.

- **Components of LiDAR:**
  - **Laser:** Emits pulses of light.
  - **Scanner:** Directs the laser pulses and collects the reflected signals.
  - **GPS:** Provides accurate positioning data.
  - **IMU (Inertial Measurement Unit):** Measures the orientation of the sensor.
- **Applications:**
  - Autonomous vehicles for obstacle detection and navigation.
  - Topographic mapping and 3D modeling.
  - Environmental monitoring.

#### 2. Hector SLAM (Simultaneous Localization and Mapping):

Hector SLAM is a method used for creating maps of an environment while simultaneously keeping track of the vehicle's location within that environment. It is particularly well-suited for real-time robotics applications because it does not rely on odometry or inertial measurements but uses the high update rate of LiDAR scans.

- **Key Features:**
  - **Robustness:** Performs well in environments with fast motion and without relying on wheel odometry.
  - **Real-Time Capability:** Suitable for high-speed operations due to its fast processing time.
  - **Accuracy:** Provides high-resolution maps and precise localization.

#### How They Work Together:

1. **Data Collection:** The LiDAR sensor continuously emits laser pulses and collects the reflected signals from the environment. This data forms a series of point clouds representing the surroundings.
2. **Scan Matching:** Hector SLAM uses scan matching techniques to align consecutive LiDAR scans. It identifies the best match between the current scan and the previously stored map.

3. **Map Updating:** As the vehicle moves, Hector SLAM updates the map in real-time by integrating new LiDAR data. It corrects any positional drift by comparing new scans to the existing map.
4. **Localization:** The system maintains an accurate estimate of the vehicle's position by continuously aligning incoming scans with the map. This enables the vehicle to navigate effectively through the environment.

## Applications:

- **Autonomous Vehicles:** LiDAR and Hector SLAM are widely used in autonomous cars and drones for navigation, obstacle avoidance, and environment mapping.
- **Robotics:** Mobile robots use this combination for indoor and outdoor navigation, ensuring precise movement and interaction with their environment.
- **Surveying and Mapping:** Used in surveying applications to create detailed maps of complex environments.

By using LiDAR for accurate distance measurements and Hector SLAM for real-time mapping and localization, autonomous systems can navigate complex environments efficiently and safely.

The screenshot shows a terminal window with a text editor open. The file is named `dwa_local_planner_params.yaml`. The code is a YAML configuration for the DWA local Planner. It includes sections for robot configuration parameters, goal tolerance, forward simulation parameters, trajectory scoring parameters, oscillation prevention parameters, and debugging. The code uses red and green syntax highlighting for comments and variables.
